Myth: a container is a small virtual machine.

It's an ordinary process on your host's kernel, with limits wrapped around it.

A developer building their own runtime found that out the fun way.

My rule: code I don't trust runs in a VM.

VM or just a process? Pick a side, then save this.

- Its processes show up in the host's /proc, Code and Cake found.
- Namespaces and cgroups fence it in, but the kernel is shared.
- One engineer's reply: processes are just abstractions too.
