Updating macOS won't fix your git. Neither will fixing it once by hand.

The git, curl and python3 that ship with macOS still trust eight compromised certificates.

Anyone on your network path could **swap the code you clone.**

Three plans, per Dennis Jackson's write-up.

Which did you try first? Save this.

- Wait for Apple: macOS 27.2 shipped without the fix.
- Fix it by hand once: 27.2 undid that fix.
- Works: fix it by hand, then rerun his git check after every update.
