File permissions won't protect your SSH keys. Neither will a password vault.

Serge Gatezh moved his keys into his Mac's Secure Enclave.

Now every SSH connection waits for his fingerprint.

Three plans, per his write-up.

Which did you try first? Save this.

- Key file in ~/.ssh: any script that reads your disk can copy it.
- Password vault: the key still gets decrypted in memory to sign.
- Works: a key made in hardware that never leaves it, Touch ID on every use.
